Programming Your GPU with OpenMP

Tom Deakin
University of Bristol
tom.deakin@bristol.ac.uk

Wei-Chen (Tom) Lin
University of Bristol

This tutorial material includes many contributors, including Simon McIntosh-Smith and Tim Mattson, Eric Stotzer from Mythic Inc, and Harry Waugh, James Price, Matt Martineau and others from the University of Bristol’s HPC Research Group.
All the tutorial materials are available online

https://github.com/uob-hpc/openmp-tutorial
Welcome to the Programming your GPU with OpenMP tutorial!

- **GPUs** are becoming increasingly important as most Exascale machines will be relying on them.
- Given there are now at least 3 mainstream GPU vendors, we need a *portable* way to program them.
- OpenMP offload support for GPUs has been maturing nicely in recent years, so this is a good time to learn how to use it.
- This will be a **hands-on tutorial**, with a mix of pre-recorded short lectures, interspersed with live exercises.
Preliminaries: Part 1

• Disclosures
  – The views expressed in this tutorial are those of the people delivering the tutorial.
    – We are not speaking for our employers.
    – We are not speaking for the OpenMP ARB

• We take these tutorials VERY seriously:
  – Help us improve … tell us how you would make this tutorial better.
Preliminaries: Part 2

• Our plan for the day .. **Active Learning!**
  – We will mix short lectures with short exercises.
  – You will use your laptop to connect to a remote system which includes GPUs.

• Please follow these simple rules
  – Do the exercises that we assign and then change things around and experiment.
    – Embrace active learning!
  – **Don’t cheat:** Do Not look at the solutions before you complete an exercise … even if you get really frustrated.
Agenda

**Morning**
- Introduction
- OpenMP overview
  - Live exercise 1
- Device model
- Moving data implicitly
- Loop directive
- Live exercise 2
- **Coffee break, 30 mins**
- Moving data explicitly
- Profiling offloaded code
- Live exercise 3

**Afternoon**
- Welcome back and recap
- Controlling data movement
- Live exercise 5
- Optimising GPU
- Live exercise 6
- **Coffee break, 30 mins**
- BUD – “Big Ugly Directive”
- Performance portability
- OpenMP 5 and ecosystem
- QA, discussion, time to finish exercises
OpenMP basic definitions: the solution stack

When OpenMP was originally launched, the focus was on Symmetric Multiprocessing, i.e. lots of threads with “equal cost access” to memory.
OpenMP programming model

Fork-Join Parallelism:

- Master thread spawns a team of threads as needed.
- Parallelism added incrementally until performance goals are met, i.e., the sequential program evolves into a parallel program.
The growth of complexity in OpenMP

- OpenMP started out in 1997 as a simple interface for the application programmers more versed in their area of science than computer science.

- The complexity has grown considerably over the years!

Supports general multithreading, but the emphasis was on parallel loops
Numerical integration: the Pi program

Mathematically, we know that:

\[ \int_{0}^{1} \frac{4.0}{(1+x^2)} \, dx = \pi \]

We can approximate the integral as a sum of rectangles:

\[ \sum_{i=0}^{N} F(x_i) \Delta x \approx \pi \]

Where each rectangle has width \( \Delta x \) and height \( F(x_i) \) at the middle of interval \( i \).
static long num_steps = 100000;
double step;
int main ()
{
    int i;    double x, pi, sum = 0.0;

    step = 1.0/(double) num_steps;

    for (i=0; i< num_steps; i++){
        x = (i+0.5)*step;
        sum = sum + 4.0/(1.0+x*x);
    }
    pi = step * sum;
}

See openmp-tutorial/pi.c
#include <omp.h>
static long num_steps = 100000; double step;
void main ()
{
    int i; double x, pi, sum = 0.0;
    step = 1.0/(double) num_steps;
    #pragma omp parallel
    {
        double x;
        #pragma omp for reduction(+:sum)
        for (i=0; i< num_steps; i++){
            x = (i+0.5)*step;
            sum = sum + 4.0/(1.0+x*x),
        }
    }
    pi = step * sum;
}
The growth of complexity in OpenMP

- OpenMP started out in 1997 as a simple interface for the application programmers more versed in their area of science than computer science.

- The complexity has grown considerably over the years!
The growth of complexity in OpenMP

- OpenMP started out in 1997 as a simple interface for the application programmers more versed in their area of science than computer science.

- The complexity has grown considerably over the years!

**Diagram:**

- Tasks added to OpenMP ... supports irregular parallelism
- Target constructs added to OpenMP ... supports host-device model
OpenMP programming model

• Up to OpenMP 3.0:
  – Aimed at multi-core CPUs
  – All cores can see all the main memory
  – So OpenMP has one memory space, available to all parallel threads
  – It’s SHARED memory programming!

• OpenMP 4.x changes this.

• Added NUMA controls:
  – Available memory doesn’t have uniform performance
  – Still shared and available to all CPU cores

• Target device model added:
  – Target device has separate memory space
  – Enables heterogenous programming
OpenMP basic definitions: the solution stack

- **User layer**
  - End User
  - Application

- **Program layer**
  - Directives, Compiler
  - OpenMP library
  - Environment variables

- **System layer**
  - OpenMP Runtime library
  - OS/system support for shared memory and threading

- **Hardware**
  - CPU cores
  - SIMD units
  - Shared address space (NUMA)
  - GPU cores
Live exercise 1

Log in to Cluster and simple CPU vector add in OpenMP
AWS Parallel Cluster

• Thanks to AWS for supporting this tutorial!

• You have access to a ParallelCluster with some NVIDIA Tesla T4 GPUs
• NVIDIA NVHPC compiler toolchain installed

• Username: trainxy (two-digit number)
• Password: iwomp23
Using our AWS ParallelCluster (1/2)

# 1) Log in to the head
ssh trainXX@54.86.126.69

# 2) Change to the directory containing the exercises
 cd openmp-tutorial

# 3) List files
 ls

[br-train01@login-01 openmp-tutorial]$ ls
heat.c  jac_solv.c  Make_def_files  mm_utils.c  Solutions
submit_jac_solv  submit_vadd  vadd_heap.c
heat_map.c  make.def  makefile  mm_utils.h  pi.c
README.md  submit_heat  submit_pi  vadd.c
...
Using our AWS ParallelCluster (2/2)

# Load the compilers (NB: you need both!)
spack load gcc@12 nvhpc

# Build the exercises
make

# Submit a job
sbatch submit_vadd

# Check job status
squeue -u $USER

<table>

(job will disappear shortly after completion)
Exercise: Simple vector add in OpenMP on CPU

Edit file: vadd.c

- Based on a simple parallel pattern: vector addition
- This adds together two arrays, element by element
- We will build on this over the next few exercises
  - Highlights the OpenMP concepts you’re learning

- Check you can log into the Cluster
- Take the serial vector add example we’ve provided, and add OpenMP worksharing directives to run in parallel on the CPU
  - #pragma omp parallel for
Solution: Simple vector add in OpenMP on CPU

Files: Solutions/vadd_par.c, Solutions/submit_vadd_par

```c
int main()
{
    float a[N], b[N], c[N], res[N];
    int err=0;

    // fill the arrays
    #pragma omp parallel for
    for (int i=0; i<N; i++){
        a[i] = (float)i;
        b[i] = 2.0*(float)i;
        c[i] = 0.0;
        res[i] = i + 2*i;
    }

    // add two vectors
    #pragma omp parallel for
    for (int i=0; i<N; i++){
        c[i] = a[i] + b[i];
    }

    // test results
    #pragma omp parallel for reduction(+:err)
    for(int i=0;i<N;i++){
        float val = c[i] - res[i];
        val = val*val;
        if(val>TOL) err++;
    }
    printf("vectors added with %d errors\n", err);
    return 0;
}
```

• Performance portability
• OpenMP 5 and ecosystem
• QA, discussion, time to finish exercises
A Generic GPU (following Hennessey and Patterson)
A Generic GPU (following Hennessey and Patterson)
The OpenMP device programming model

• OpenMP uses a host/device model
  – The *host* is where the initial thread of the program begins execution
  – Zero or more *devices* are connected to the host
  – Device-memory address space is distinct from host-memory address space

```c
#include <omp.h>
#include <stdio.h>
int main()
{
    printf("There are %d devices\n", omp_get_num_devices());
}
```
OpenMP with target devices

- The target construct offloads execution to a device.

```
#pragma omp target
{....} // a structured block of code
```

1. Program begins. Launches initial thread running on the host device.
2. Implicit parallel region surrounds entire program.
3. Initial task begins execution.
4. Initial task encounters the target directive.
5. Initial task generates a target task which is a mergable, included task.
6. Target task launches target region on the device.
7. A new initial thread runs on the device.
8. Implicit parallel region surrounds device program.
9. Initial task executes code in the target region.
10. Initial task on host continues once execution associated with the target region completes.
Running code on the GPU: The target construct and default data movement

```
float A[N], B[N];
#pragma omp target {
    Target task
}
```

Host thread waits for the task region to complete

Initial task

```
A, B and N mapped to the device
```

Device Initial thread

```
{ target region, can use A, B and N }
```

Only the statically allocated arrays are moved back to the host after the target region completes

 Scalars and statically allocated arrays are moved onto the device by default before execution

Based on figure 6.4 in *Using OpenMP – The Next Step* by van der Pas, Stotzer and Terboven, MIT Press, 2017
The ‘target data’ environment

• **Remember**: there are distinct memory spaces on host and device.

• OpenMP uses a combination of *implicit* and *explicit* data movement.

• Data may move between the host and the device in well defined places:
  – Firstly, at the beginning and end of a **target** region:

    ```cpp
    #pragma omp target
    {
        // Data may move from host to device here
        ...
    }
    // and from device to host here
    
    • We’ll discuss the other places later…
Default Data Mapping: implicit movement with a target region

• Scalar variables:
  – Examples:
    – int N; double x;

  – OpenMP implicitly maps scalar variables as **firstprivate**
    – A new value per work-item is initialized with the original value (in OpenCL nomenclature, the firstprivate goes in private memory).

  – The variable is **not** copied back to the host at the end of the target region.

  – In CUDA/OpenCL parlance, a firstprivate scalar can be launched as a parameter to a kernel function without the overhead of setting up a variable in device memory.
Default Data Mapping:
implicit movement with a target region

• Non-scalar variables:
  – Must have a **complete type**.

  – Example: fixed sized (stack) array:
    – double A[1000];

  – Copied to the device at the start of the **target** region, *and* copied back at the end. In OpenCL nomenclature, these are placed in device global memory.

  – A new memory object is created in the target region and initialized with the original data, but it is shared between threads on the device. Data is copied back to the host at the end of the target region.

  – OpenMP calls this mapping **tofrom**
Default Data Mapping:

implicit movement with a target region

• Pointers are implicitly copied, but not the data they point to:

  – Example: arrays allocated on the heap
    – double *A = malloc(sizeof(double)*1000);

  – The pointer value will be mapped (i.e. the address stored in A).

  – But the data it points to will not be mapped by default.

  – We’ll show you how to map a pointer’s data shortly.
Running code on the GPU:
The target construct and default data movement

**Host thread**

Generating Task

```
float A[N], B[N];
#pragma omp target
{
    A, B and N mapped to the device
    target region, can use A, B and N
}
```

**Device Initial thread**

Initial task

Target task

```
}  
the arrays A and B mapped back to the host
```

Scalars and statically allocated arrays are moved onto the device by default before execution

Only the statically allocated arrays are moved back to the host after the target region completes

Based on figure 6.4 in *Using OpenMP – The Next Step* by van der Pas, Stotzer and Terboven, MIT Press, 2017
int main(void) {
    int N = 1024;
    double A[N], B[N];

    #pragma omp target
    {
        for (int ii = 0; ii < N; ++ii) {
        }
    } // end of target region

} // end of target region

1. Variables created in host memory.

2. Scalar N and stack arrays A and B are copied to device memory. Execution transferred to device.

3. ii is private on the device as it’s declared within the target region

4. Execution on the device.

5. Stack arrays A and B are copied from device memory back to the host. Host resumes execution.
Commonly used clauses with target

```c
#pragma omp target [clause[,clause]...] structured-block
```

- `if(scalar-expression)`
  - If the scalar-expression evaluates to false then the target region is executed by the host device in the host data environment.

- `device(integer-expression)`
  - The value of the integer-expression selects the device when a device other than the default device is desired.

- `private(list) firstprivate(list)`
  - Creates variables with the same name as those in the list on the device. In the case of `firstprivate`, the value of the variable on the host is copied into the private variable created on the device.

- `map(map-type: list)`
  - `map-type` may be `to`, `from`, `tofrom`, or `alloc`. The clause defines how the variables in list are moved between the host and the device. (Lots more on this later)...

- `nowait`
  - The target task is deferred which means the host can run code in parallel to the target region on the device.
Let’s run code in parallel on the device

```c
int main(void) {
    int N = 1024;
    double A[N], B[N], C[N];

    #pragma omp target
    #pragma omp loop
    for (int ii = 0; ii < N; ++ii) {
    }
}
```

The loop construct tells the compiler:

"this loop will execute correctly if the loop iterations run in any order. You can safely run them **concurrently**. And the loop-body doesn’t contain any OpenMP constructs. So do whatever you can to make the code run fast"

The loop construct is a declarative construct. You tell the compiler what you want done but you DO NOT tell it how to “do it”. This is new for OpenMP
Live exercise 2

Vector add on a GPU
Exercise: Parallel vector addition on a GPU

Edit file: vadd.c

• Make a copy of your parallel vadd.c program for a CPU (i.e. save the CPU version)
  - vadd.c Adds together two arrays, element by element: for(i=0;i<N;i++) c[i]=a[i]+b[i];
• Parallelize your vadd program for a GPU
• Time it for large N and save the result. How does it compare to the CPU version?
  - double omp_get_wtime();
  - #pragma omp parallel
  - #pragma omp for
  - #pragma omp parallel for
  - #pragma omp target
  - #pragma omp loop

For tiny little programs, OpenMP may opt to run the code on the host. You can force the OpenMP runtime to use the GPU by setting the OMP_TARGET_OFFLOAD environment variable

> OMP_TARGET_OFFLOAD=MANDATORY ./a.out
Solution: Simple vector add in OpenMP on GPU

Files: Solutions/vadd_target.c, Solutions/submit_vadd_target

```c
int main()
{
    float a[N], b[N], c[N], res[N];
    int err=0;

    // fill the arrays
    #pragma omp parallel for
    for (int i=0; i<N; i++){
        a[i] = (float)i;
        b[i] = 2.0*(float)i;
        c[i] = 0.0;
        res[i] = i + 2*i;
    }

    // add two vectors
    #pragma omp target
    #pragma omp loop
    for (int i=0; i<N; i++){
        c[i] = a[i] + b[i];
    }

    // test results
    #pragma omp parallel for reduction(+:err)
    for(int i=0;i<N;i++){
        float val = c[i] - res[i];
        val = val*val;
        if(val>TOL) err++;
    }
    printf("vectors added with %d errors\n", err);
    return 0;
}
```

Explicit data movement

- Previously, we described the rules for *implicit* data movement.

- We can *explicitly* control the movement of data using the `map` clause.

- **Data allocated on the heap needs to be explicitly copied to/from the device:**

```c
int main(void) {
    int ii=0, N = 1024;
    int* A = malloc(sizeof(int)*N);

    #pragma omp target
    {
        // N, ii and A all exist here
        // The data that A points to (*A, A[ii]) *DOES NOT* exist here!
    }
}
```
Moving data with the map clause

```c
int main(void) {
    int N = 1024;
    int* A = malloc(sizeof(int)*N);

    #pragma omp target map(A[0:N])
    {
        // N, ii and A all exist here
        // The data that A points to DOES exist here!
    }
}
```

Default mapping
map(tofrom: A[0:N])
Copy at start and end of target region.
OpenMP array notation

• For mapping data arrays/pointers you must use array section notation:
  – In C, notation is `pointer[lower-bound : length]`
  – `map(to: a[0:N])`
    – Starting from the element at `a[0]`, copy `N` elements to the target data region

  – **Be careful!**
    – Common to misremember this as `begin : end`, but it is `length`

  – Without the map, OpenMP defines that the pointer itself (`a`) is mapped as a zero-length array section.
    – Zero length arrays: `A[:0]`
Controlling data movement

int i, a[N], b[N], c[N];
#pragma omp target map(to:a,b) map(tofrom:c)

- The various forms of the map clause
  - map(to:list): On entering the region, variables in the list are initialized on the device using the original values from the host (host to device copy).
  - map(from:list): At the end of the target region, the values from variables in the list are copied into the original variables on the host (device to host copy). On entering the region, the initial value of the variables on the device is not initialized.
  - map(tofrom:list): the effect of both a map-to and a map-from (host to device copy at start of region, device to host copy at end).
  - map(alloc:list): On entering the region, data is allocated and uninitialized on the device.
  - map(list): equivalent to map(tofrom:list).
5-point stencil: the heat program

• The heat equation models changes in temperature over time.

\[
\frac{\partial u}{\partial t} - \alpha \nabla^2 u = 0
\]

• We'll solve this numerically on a computer using an explicit finite difference discretisation.

• \(u = u(t, x, y)\) is a function of space and time.

• Partial differentials are approximated using diamond difference formulae:

\[
\frac{\partial u}{\partial t} \approx \frac{u(t + 1, x, y) - u(t, x, y)}{dt}
\]

\[
\frac{\partial^2 u}{\partial x^2} \approx \frac{u(t, x + 1, y) - 2u(t, x, y) + u(t, x - 1, y)}{dx^2}
\]

- Forward finite difference in time, central finite difference in space.
5-point stencil: the heat program

• Given an initial value of $u$, and any boundary conditions, we can calculate the value of $u$ at time $t+1$ given the value at time $t$.
• Each update requires values from the north, south, east and west neighbours only:

• Computation is essentially a weighted average of each cell and its neighbouring cells.
• If on a boundary, look up a boundary condition instead.
5-point stencil: solve kernel

```cpp
void solve(...) {
    // Finite difference constant multiplier
    const double r = alpha * dt / (dx * dx);
    const double r2 = 1.0 - 4.0*r;

    // Loop over the nxn grid
    for (int i = 0; i < n; ++i) {
        for (int j = 0; j < n; ++j) {

            // Update the 5-point stencil, using boundary conditions on the edges of the domain.
            // Boundaries are zero because the MMS solution is zero there.
            u_tmp[i+j*n] = r2 * u[i+j*n] +
                            r * ((i < n-1) ? u[i+1+j*n] : 0.0) +
                            r * ((i > 0)   ? u[i-1+j*n] : 0.0) +
                            r * ((j < n-1) ? u[i+(j+1)*n] : 0.0) +
                            r * ((j > 0)   ? u[i+(j-1)*n] : 0.0);
        }
    }
}
```

Profiling GPU code

• Host-to-device transfers are important to optimize
  – Main memory bandwidth of device is typically high
    – P100 has peak of 732 GB/s
  – But memory bandwidth between host and device is usually much lower
    – PCIe 3.0 x16 has peak of 32 GB/s

• Knowing the code, we can predict that all the data movement between the host and device takes a lot of time

• Want to use tools to find this out for certain
CUDA Toolkit

Cray maps their OpenMP constructs onto CUDA so NVIDIA’s CUDA toolkit works with the Cray compilers.

We will demonstrate using an OpenMP version of flow

Hydrodynamics mini-app solving Euler’s compressible equations

Explicit 2D method that uses various stencils, keeping data resident on GPU for entire solve
CUDA Toolkit: NVProf

Simple profiling: nvprof ./exe <params>

> nvprof ./flow.omp4 flow.params
Problem dimensions 4000x4000 for 1 iterations.
==188532== NVPROF is profiling process 188532, command: ./flow.omp4 flow.params
Number of ranks: 1
Number of threads: 1

Iteration 1
Timestep: 1.816932845523e-04
Total mass: 2.561400875000e+06
Total energy: 5.44284982081e+06
Simulation time: 0.0001s
Wallclock: 0.0325s

Expected energy 3.231871108096e+07, result was 3.231871108096e+07.
Expected density 2.561400875000e+06, result was 2.561400875000e+06.
PASSED validation.
Wallclock 0.0325s, Elapsed Simulation Time 0.0001s

Nvidia has deprecated their wonderful command line tool for profiling GPU programs.

We can still get profiling information with the nsys tool:

> nsys ./a.out
> nsys nvprof ./a.out
Live exercise 3

Parallelising stencil on a GPU
Exercise: parallel stencil (heat)

Files: heat.c

• Take the provided heat stencil code (heat.c)
• Add OpenMP directives to parallelize the loops on the GPU
• Add OpenMP map clauses to copy data between host and device
• Most of the runtime occurs in the solve() routine

• Directives and clauses:
  – #pragma omp target
  – #pragma omp target map
  – #pragma omp loop
  – #pragma omp loop collapse

• Experiment with problem size and the profiler:
  – Where is the bottleneck?
  – Note, on Isambard, the profile can be run by nsys nvprof --profile-child-processes ./heat
Exercise: heat code inputs

Files: heat.c

• Takes two optional command line arguments: <ncells> <nsteps>
  – E.g. ./heat 1000 10
  – 1000x1000 cells, 10 timesteps (the default problem size).

• If no command line arguments are provided, it uses a default:
  – These two commands both run the default problem size of 1000x1000 cells, 10 timesteps.
  – ./heat
  – ./heat 1000 10

• A sensible bigger problem is 8000 x 8000 cells and 10 timesteps.

• Edit submit_heat to change the problem size

• If you try other problems, change the code to report $r < 0.5$.
  – A warning is printed if this is not the case.
Solution: parallel stencil (heat)

Files: Solutions/heat_target.c, Solutions/submit_heat_target

// Compute the next timestep, given the current timestep
void solve(const int n, const double alpha, const double dx, const double dt, const double * restrict u, double * restrict u_tmp) {
    // Finite difference constant multiplier
    const double r = alpha * dt / (dx * dx);
    const double r2 = 1.0 - 4.0*r;

    // Loop over the nxn grid
    #pragma omp target map(tofrom: u[0:n*n], u_tmp[0:n*n])
    #pragma omp loop collapse(2)
    for (int i = 0; i < n; ++i) {
        for (int j = 0; j < n; ++j) {
            // Update the 5-point stencil, using boundary conditions on the edges of the domain.
            // Boundaries are zero because the MMS solution is zero there.
            u_tmp[i+j*n] = r2 * u[i+j*n] +
            r * ((i < n-1) ? u[i+1+j*n] : 0.0) +
            r * ((i > 0) ? u[i-1+j*n] : 0.0) +
            r * ((j < n-1) ? u[i+(j+1)*n] : 0.0) +
            r * ((j > 0) ? u[i+(j-1)*n] : 0.0);
        }
    }
}
Solution: nsys

```bash
$ nsys nvprof ./heat_map_target 8000 10
```

Data movement dominates!

for (int t = 0; t < nsteps; ++t) {
    solve(n, alpha, dx, dt, u, u_tmp);
    // Pointer swap
    tmp = u;
    u = u_tmp;
    u_tmp = tmp;
}

Typically lots of iterations!

For each iteration, copy to device
(2*N^2)*sizeof(TYPE) bytes

solve() routine uses this pragma:
#pragma omp target map(u_tmp[0:n*n], u[0:n*n])
solve(n, alpha, dx, dt, u, u_tmp);

For each iteration, copy from device
(2*N^2)*sizeof(TYPE) bytes

Next topic: how to keep data resident on
target device between target regions
Welcome back and recap (5min)
Agenda

**Morning**
- Introduction
- OpenMP overview
- Live exercise 1
- Device model
- Moving data implicitly
- Loop directive
- Live exercise 2
- **Coffee break, 30 mins**
- Moving data explicitly
- Profiling offloaded code
- Live exercise 3

**Afternoon**
- Welcome back and recap
- Controlling data movement
- Live exercise 4
- Optimising GPU
- Live exercise 5
- **Coffee break, 30 mins**
- BUD – “Big Ugly Directive”
- Performance portability
- OpenMP 5 and ecosystem
- QA, discussion, time to finish exercises
Finer control over data movement

- Recall that data is mapped to/from device at start/end of target region
  - #pragma omp target map(tofrom: A[0:N])
    
    ```
    {
      ...
    }
    ```

- Inefficient to move data around all the time
- Want to keep data resident on the device between target regions
- Will explain how to interact with the device data environment
**Target data directive**

- The **target data** construct creates a target data region
  ... use **map** clauses for explicit data management

```plaintext
#pragma omp target data map(to:A[0:N], B[0:M]) map(from: C[0:P])
{
    #pragma omp target
    {do lots of stuff with A, B and C}

    {do something on the host}

    #pragma omp target
    {do lots of stuff with A, B, and C}
}
```

Data is mapped onto the device at the beginning of the construct

Data is mapped back to the host at the end of the target data region

One or more **target regions** work within the **target data region**
#pragma omp target update clause[[[,]clause]...]  
- Creates a target task to handle data movement between the host and a device.

- clause is either a motion-clause:  
  - to(list)  
  - from(list)

- Or one of the following:  
  - if(scalar-expression)  
  - device(integer-expression)  
  - nowait  
  - depend (dependence-type : list)

- nowait and depend apply to the target task running on the host.
Target update directive

• You can update data between target regions with the **target update** directive.

```c
#pragma omp target data map(to: A[0:N], B[0:M]) map(from: C[0:P])
{
    #pragma omp target
    {do lots of stuff with A, B and C on the device}

    #pragma omp target update from(A[0:N])
    host_do_something_with(A)

    #pragma omp target update to(A[0:N])

    #pragma omp target
    {do lots more stuff with A, B, and C on the device}
}
```

Set up the data region ahead of time.

- Map A on the device to A on the host.
- Map A on the host to A on the device.

Note: update directive has the transfer direction as the clause: e.g. update to(…)
Compare to map clause with direction inside: map(to: …)
Target enter/exit data constructs

• The **target data** construct requires a *structured* block of code.
  – Often inconvenient in real codes.

• Can achieve similar behavior with two standalone directives:
  
  ```
  #pragma omp target enter data map(...) 
  #pragma omp target exit data map(...) 
  ```

• The **target enter data** maps variables to the device data environment.
• The **target exit data** unmaps variables from the device data environment.
• Future **target** regions inherit the existing data environment.
Target enter/exit data example

```c
void init_array(int *A, int N) {
    for (int i = 0; i < N; ++i)
        A[i] = i;
    //pragma omp target enter data map(to: A[0:N])
}

int main(void) {
    int N = 1024;
    int *A = malloc(sizeof(int) * N);
    init_array(A, N);

    //pragma omp target teams distribute parallel for simd
    for (int i = 0; i < N; ++i)

    //pragma omp target exit data map(from: A[0:N])
}
```
Target enter/exit data details

- `#pragma omp target enter data clause[[[,]clause]...]`
- Creates a target task to handle data movement between the host and a device.

- `clause` is one of the following:
  - `if(scalar-expression)`
  - `device(integer-expression)`
  - `nowait`
  - `depend (dependence-type : list)`
  - `map (map-type: list)`

- `nowait` and `depend` apply to the target task running on the host.
A note about the nowait clause

• Specify dependencies to ensure the **target enter data** finishes *before* the **target** region *sibling* task starts:

```c
void init_array(int *A, int N) {
    for (int i = 0; i < N; ++i) A[i] = i;
    #pragma omp target enter data map(to: A[0:N]) nowait depend(out: A)
}

int main(void) {
    int N = 1024; int *A = malloc(sizeof(int) * N);
    init_array(A, N);

    #pragma omp target teams distribute parallel for simd nowait depend(inout: A)
    for (int i = 0; i < N; ++i) A[i] = A[i] * A[i];

    #pragma omp taskwait

    #pragma omp target exit data map(from: A[0:N])
}
```
Notes about Pointer swapping

- Mapping between addresses on host and device is done when the target constructs are **encountered**
- `#pragma omp target data map(from: )`
  - The from location is **fixed** from the **start** of the target data region
  - If pointers are swapped, data is still copied back to the original pointer

```c
void *orig = a;  
#pragma omp target data map(tofrom: a[0:N])  
{
    a = NULL;  // or anything else
}
```

- Target exit data map(from: ) uses the **current** mapping
  - So if pointers are swapped, it will go to the **new** address
Data movement summary

- Data transfers between host/device occur at:
  - Beginning and end of **target** region
  - Beginning and end of **target data** region
  - At the **target enter data** construct
  - At the **target exit data** construct
  - At the **target update** construct

- Can use **target data** and **target enter/exit data** to reduce redundant transfers.

- Use the **target update** construct to transfer data on the fly within a **target data** region or between **target enter/exit data** directives.
Live exercise 4

Optimising stencil data movement
Exercise
Files: heat.c

• Modify your parallel heat code from the last exercise.
• Use the ‘target data’ family of constructs to control the device data environment.
• Minimize data movement with map clauses to minimize data movement.

− #pragma omp target
− #pragma omp target enter data
− #pragma omp target exit data
− #pragma omp target update
− map(to:list) map(from:list) map(tofrom:list)
− #pragma omp loop
Solution: Pointer swapping in action

Files: Solutions/heat_target_map.c, Solutions/submit_heat_target_map

```c
#pragma omp target enter data map(to: u[0:n*n], u_tmp[0:n*n])

for (int t = 0; t < nsteps; ++t) {

    solve(n, alpha, dx, dt, u, u_tmp);

    // Pointer swap
    tmp = u;
    u = u_tmp;
    u_tmp = tmp;

    #pragma omp target exit data map(from: u[0:n*n])
```

Copy data to device before iteration loop

Update solve() routine to remove map clauses:

```c
#pragma omp target map(u_tmp[0:n*n], u[0:n*n])
```

Copy data from device after iteration loop

Pointer-swap on the host works. Why?
The pointers (u and u_tmp) are “on the stack” scalars the value of which is a pointer to memory. They are copied onto the device at the target construct.
The association between host and device addresses is fixed with the start of a target data region. Hence, as you swap the pointers, the references to the addresses in device memory are swapped ….. i.e. pointer-swapping on the host works.
NVPROF output

Data movement summary

- Data transfers between host/device occur at:
  - Beginning and end of target region
  - Beginning and end of target data region
  - At the target enter data construct
  - At the target exit data construct
  - At the target update construct

- Can use target data and target enter/exit data to reduce redundant transfers.

- Use the target update construct to transfer data on the fly within a target data region or between target enter/exit data directives.
Getting the data movement between host memory and device memory is key.

What are the other major issues to consider when optimizing performance?

Occupyancy: Keep all the GPU resources busy

- In our “GPU cartoon” we have 16 multithreaded SIMD processors each with 16 SIMD lanes .... For a total of $16^2 = 256$ processing elements.
- You want all resources busy at all times. You do that by keeping excess work for the multithreaded SIMD processors ... if they are other busy on some high latency operation, you want a new work-group is ready to be scheduled for execution.
- **Occupyancy** having enough work-groups to keep the GPU busy. To support high occupancy, you need many more work-items than SIMD-lanes.

```c
#pragma omp parallel for
define
for(int i=0;i<N;i++)
for(int j=0;j<N;j++)
for(int k=0;k<N;k++)
*(C+(i*N+j)) += *(A+(i*N +k)) * *(B+(k*N +j));
```

- **Parallelize i-loop parallelism O(N)**
- **Parallelize combined i/j-loops**

```c
#pragma omp parallel for collapse(2)
define
for(int i=0;i<N;i++)
for(int j=0;j<N;j++)
for(int k=0;k<N;k++)
*(C+(i*N+j)) += *(A+(i*N +k)) * *(B+(k*N +j));
```

- **Parallelize i/j-loops parallelism O(N^2)**
Single Instruction Multiple Data

- Individual work-items of a warp start together at the same program address
- Each work-item has its own instruction address counter and register state
  - Each work-item is free to branch and execute independently
  - Supports the Single Program Multiple Data (SPMD) pattern.
- Branch behavior
  - Each branch will be executed serially
  - Work-items not following the current branch will be disabled
Branching

• GPUs tend not to support speculative execution, which means that branch instructions have high latency
• This latency can be hidden by switching to alternative work-items/work-groups, but avoiding branches where possible is still a good idea to improve performance
• When different work-items executing within the same SIMD ALU array take different paths through conditional control flow, we have divergent branches (vs. uniform branches)
• Divergent branches are bad news: some work-items will stall while waiting for the others to complete
• We can use predication, selection and masking to convert conditional control flow into straight line code, potentially improving the performance of code that has lots of conditional branches inside the loops
Branching

Conditional execution

// Only evaluate expression
// if condition is met
if (a > b)
{
    acc += (a - b*c);
}

Selection and masking

// Always evaluate expression
// and mask result
temp = (a - b*c);
mask = (a > b ? 1.f : 0.f);
acc += (mask * temp);
Coalesced memory accesses

- **Coalesced memory accesses** are key for high performance code, especially on GPUs

- In principle, this is very simple, but often requires transposing or transforming data on the host before sending it to the GPU

- Sometimes this is about **Array of Structures** vs. **Structure of Arrays** (**AoS** vs. **SoA**)
Memory layout is critical to performance

• Structure of Arrays vs. Array of Structures
  – **Array of Structures** (AoS) more natural to code:
    ```c
    struct Point{ float x, y, z, a; };
    Point *Points;
    ```
    ```
    x y z a ... x y z a ... x y z a ... x y z a ... 
    ```
  – **Structure of Arrays** (SoA) suits memory coalescence in vector units:
    ```c
    struct { float *x, *y, *z, *a; } Points;
    ```
    ```
    x x x x ... y y y y ... z z z z ... a a a a ... 
    ```
    Adjacent work-items/vector-lanes like to access adjacent memory locations.
Coalescence

- **Coalesce** - to combine into one
- Coalesced memory accesses are key for high bandwidth
- Simply, it means, if thread $i$ accesses memory location $n$ then thread $i+1$ accesses memory location $n+1$
- In practice, it’s not quite as strict…

```c
for (int id = 0; id < size; id++)
{
    // ideal
    float val1 = memA[id];

    // still pretty good
    const int c = 3;
    float val2 = memA[id + c];

    // stride size is not so good
    float val3 = memA[c*id];

    // terrible
    const int loc = some_strange_func(id);
    float val4 = memA[loc];
}
```
Memory access patterns

![Diagram showing GPU Threads and GPU Memory with 64 Byte Boundary]

- **GPU Threads**: 0, 1, 2, 3, 4, 5, 6, 7
- **GPU Memory**: 0x0f4, 0x0f8, 0x0fc, 0x100, 0x104, 0x108, 0x110, 0x114, 0x118, 0x120, 0x124, 0x128
- **64 Byte Boundary**
float val1 = memA[id];

64 Byte Boundary
Memory access patterns

```c
const int c = 3;
float val2 = memA[id + c];
```
float val3 = memA[3*id];

64 Byte Boundary

Strided access results in multiple memory transactions (and kills throughput)
Memory access patterns

```cpp
const int loc =
    some_strange_func(id);

float val4 = memA[loc];
```
Live exercise 5

Optimising stencil compute code
Exercise

Files: heat.c

• Optimize the stencil ‘solve’ kernel.

• Start with your code with optimized memory movement from the last exercise.

• Experiment with the optimizations we’ve discussed.

• **Focus on the memory access pattern.**

• Try different input sizes to see the effect of the optimizations.

• Keep an eye on the solve time as reported by the application.
Solution: swap loop order

Files: Solutions/heat_target_map_opt.c, Solutions/submit_heat_target_map_opt

// Compute the next timestep, given the current timestep
void solve(const int n, const double alpha, const double dx, const double dt, const double * restrict u, double * restrict u_tmp) {
    // Finite difference constant multiplier
    const double r = alpha * dt / (dx * dx);
    const double r2 = 1.0 - 4.0*r;

    // Loop over the nxn grid
    #pragma omp target
    #pragma omp loop collapse(2)
    for (int j = 0; j < n; ++j) {
        for (int i = 0; i < n; ++i) {
            // Update the 5-point stencil, using boundary conditions on the edges of the domain.
            // Boundaries are zero because the MMS solution is zero there.
            u_tmp[i+j*n] = r2 * u[i+j*n] +
                r * ((i < n-1) ? u[i+1+j*n] : 0.0) +
                r * ((i > 0) ? u[i-1+j*n] : 0.0) +
                r * ((j < n-1) ? u[i+(j+1)*n] : 0.0) +
                r * ((j > 0) ? u[i+(j-1)*n] : 0.0);
        }
    }
}

Swap the i and j loops so that the i+j*n memory accesses are contiguous

The loop construct is great, but sometimes you want more control.
OpenMP device model: Examples

Some key devices that were considered when designing the device model in OpenMP

Target Device: Intel® Xeon Phi™ processor

Target Device: GPU
OpenMP Device Model: another example

Heterogeneous System on Chip (SoC)
A Generic Host/Device Platform Model

• One **Host** and one or more **Devices**
  – Each Device is composed of one or more **Compute Units**
  – Each Compute Unit is divided into one or more **Processing Elements**

• Memory is divided into **host memory** and **device memory**
Explosion of parallelism

- GPUs are made of many cores (compute units)
  - NVIDIA V100 has 80 Streaming Multiprocessors (SMs); these are the compute units
  - NVIDIA A100 has 108 compute units
  - Each NVIDIA compute unit has 64 FP32 processing elements
  - GPUs from AMD and Intel have similar structure of compute units and processing elements
- On an A100, that’s 108 x 64 = 6.912 processing elements available to work in parallel

- Typically you need to expose multiple units of work per processing element for best performance

- Massive amount of (hierarchical) parallelism to exploit
Our host/device Platform Model and OpenMP

- **parallel for simd**: to run each block of loop iterations on the processing elements
- **teams**: construct to create a league of teams with one team of threads on each compute unit
- **distribute**: construct to assign blocks of loop iterations to teams

---

**Diagram:**
- **Host**: Central processing unit
- **Device**: A collection of compute units
- **Processing Element**: Individual processing units within the device
- **Compute Unit**: A compute unit within the device

**Simplified Explanation:**
- **Target construct**: to get onto a device
- **Construct to**: create a league of teams with one team of threads on each compute unit
Our host/device Platform Model and OpenMP

Typical usage ... let the compiler do what’s best for the device:

```c
#pragma omp target
```

```
#pragma omp teams distribute parallel for simd
```

to assign work to the device processing elements

to run each block of loop iterations on the processing elements

```c
#pragma omp target
```

```
#pragma omp teams distribute parallel for simd
```

to assign work to the device processing elements

to create a league of teams with one team of threads on each compute unit.
Implementation details

• OpenMP defines parallelism abstraction
  – Specific terminology is used

• An OpenMP implementation (runtime/compiler) has some freedom in how these are applied to hardware
  – Allows the implementation to make sensible choices to get the best performance

• OpenMP directives operate along spectrum of descriptive and prescriptive control

• Will now explain parallelism in the OpenMP abstraction
  – Will talk about how they correlate with hardware later…
Parallel threads

- Recall fork-join model and parallel regions on a CPU:
  - `#pragma omp parallel`
- Threads are created on entry to parallel region
- All those threads belong to one **team**
- Threads in a team can synchronize:
  - `#pragma omp barrier`

```
#pragma omp target
#pragma omp parallel for
for (i=0;i<N;i++)
...
```

Transfer control of execution to a **SINGLE** device thread
Only one **team** of threads workshares the loop
‘teams’ and ‘distribute’ constructs

• The **teams** construct
  – Similar to the **parallel** construct
  – It starts a league of **teams**
  – Each team in the league starts with one initial thread – i.e. a team of one thread
  – Threads in different teams **cannot** synchronize with each other
  – The construct must be “perfectly” nested in a **target** construct

• The **distribute** construct
  – Similar to the **for** construct
  – Loop iterations are workshared across the initial threads in a league
  – No implicit barrier at the end of the construct
  – **dist_schedule(kind[, chunk_size])**
    – If specified, scheduling kind must be static
    – Chunks are distributed in round-robin fashion in chunks of size **chunk_size**
    – If no chunk size specified, chunks are of (almost) equal size; each team receives at least one chunk
Multiple teams

• teams construct
• distribute construct

```
#pragma omp target
#pragma omp teams
#pragma omp distribute
for (i=0;i<N;i++)
...
```

• Transfer execution control to MULTIPLE device initial threads
• Workshare loop iterations across the initial threads.

Note: number of teams is implementation defined, good for portable performance. Compilers can choose how they map teams and threads.
Putting it together

• teams distribute
• parallel for simd

Transfer execution control to **MULTIPLE** device initial threads (one per team)
  – Workshare loop iterations across the initial threads (teams distribute)

• Each initial thread becomes the master thread in a thread team
  – Workshare loop iterations across the threads in a team (parallel for simd)

```c
#pragma omp target
#pragma omp teams distribute
for (i=0;i<N;i++)
#pragma omp parallel for simd
for (j=0;j<M;j++)
...
```
Composite Constructs

• The distribution patterns can be cumbersome
• OpenMP defines composite constructs for typical code patterns
  – distribute simd
  – distribute parallel for
  – distribute parallel for simd
  – ... plus additional combinations for teams and target
• Let the compiler figure out the loop tiling

```c
#pragma omp target teams
{
    #pragma omp distribute parallel for simd
    for (int i = 0; i < n; i++) {
        F(i) = G(i);
    }
}
```
Worksharing example

```
#pragma omp target teams distribute parallel for simd
num_teams(2) num_threads(4) simdlen(2)
for (i=0; i<64; i++)
...
```

64 iterations assigned to 2 teams; Each team has 4 threads; Each thread has 2 SIMD lanes

**Distribute** iterations across 2 teams

![Distribute iterations across 2 teams diagram]

In a team, **workshare** (parallel for) iterations across 4 threads

![In a team, workshare (parallel for) iterations across 4 threads diagram]

In each thread use **SIMD** parallelism

![In each thread use SIMD parallelism diagram]
Commonly used clauses on teams distribute parallel for simd

• The basic construct* is:

```
#pragma omp teams distribute parallel for simd [clause[[[,]clause]...]
for-loops
```

• The most commonly used clauses are:

  – `private(list) firstprivate(list) lastprivate(list) shared(list)`
    - behave as data environment clauses in the rest of OpenMP, but note values are only created or copied into the region, not back out “at the end”.

  – `reduction(reduction-identifier : list)`
    - behaves as in the rest of OpenMP … but the variable must appear in a map(tofrom) clause on the associated target construct in order to get the value back out at the end (more on this later)

  – `collapse(n)`
    - Combines loops before the distribute directive splits up the iterations between teams

  – `dist_schedule(kind[, chunk_size])`
    - only supports kind = static. Otherwise works the same as when applied to a for construct. Note: this applies to the operation of the distribute directive and controls distribution of loop iterations onto teams (NOT the distribution of loop iterations inside a team).

*We often refer to this as the Big Ugly Directive, or BUD
There is MUCH more … beyond what have time to cover

• Do as much as you can with a simple loop construct. It’s portable and as compilers improve over time, it will keep up with compiler driven performance improvements.

• But sometimes you need more:
  – Control over number of teams in a league and the size of the teams
  – Explicit scheduling of loop iterations onto the the teams
  – Management of data movement across the memory hierarchy: global vs. shared vs. private …
  – Calling optimized math libraries (such as cuBLAS)
  – Multi-device programming
  – Asynchrony

• Ultimately, you may need to master all those advanced features of GPU programming. But start with loop. Start with how data on the host maps onto the device (i.e. the GPU). Master that level of GPU programming before worrying about the complex stuff.

Recall OpenMP device model

Uses OpenCL terminology, but describes a generic GPU:
- Two levels of parallelism:
  - Compute Units
  - Processing Elements
- Processing elements in a compute unit typically operate in lock-step
  - But not necessarily, e.g. NVIDIA Volta architecture
  - Performance typically lower when they don’t
## GPU terminology is Broken (sorry about that)

SIMT: Single Instruction, Multiple Thread

- SIMT model: Individual scalar instruction streams are grouped together for SIMD execution on hardware.
Executing a program on CPUs and GPUs

Program defines work

For a CPU

Work decomposed into blocks

For a GPU

Work decomposed into work-items

Organized into work-groups

One work-group per compute-unit executing
Executing a program on CPUs and GPUs

Program defines work

Work decomposed into blocks

Mapped onto threads for execution

For a CPU

Work decomposed into work-items

Organized into work-groups

Enqueued for execution

For a GPU

One work-group per compute-unit executing
CPU/GPU execution model

For a CPU, the threads are all active and able to make forward progress.

For a GPU, any given work-group might be in the queue waiting to execute.
How do we execute code on a GPU:
The SIMT model (Single Instruction Multiple Thread)

1. Turn source code into a scalar work-item

```c
extern void reduce( __local float*, __global float* );

__kernel void pi( const int niters, float step_size,
                  __local float* l_sums, __global float* p_sums)
{
    int n_wrk_items = get_local_size(0);
    int loc_id = get_local_id(0);
    int grp_id = get_group_id(0);
    float x, accum = 0.0f, int i,istart,iend;
    istart = (grp_id*n_wrk_items + loc_id)*niters;
    iend = istart+niters;
    for(i=istart; i<iend; i++){
        x = (i+0.5f)*step_size; accum += 4.0f/(1.0f+x*x); }
    l_sums[loc_id] = accum;
    barrier(CLK_LOCAL_MEM_FENCE);
    reduce(l_sums, p_sums);
}
```

This is OpenCL kernel code … the sort of code the OpenMP compiler generates on your behalf

2. Map work-items onto an N dimensional index space

3. Map data structures onto the same index space

4. Run on hardware designed around the same SIMT execution model
How do we execute code on a GPU: OpenCL and CUDA nomenclature

Turn source code into a scalar work-item (a CUDA thread)

```c
extern void reduce( __local float*, __global float*);
__kernel void pi( const int niters, float step_size,
                 __local float* l_sums, __global float* p_sums)
{
    int n_wrk_items = get_local_size(0);
    int loc_id = get_local_id(0);
    int grp_id = get_group_id(0);
    float x, accum = 0.0f;  int i,istart,iend;
    istart = (grp_id * n_wrk_items + loc_id) * niters;
    iend = istart+niters;
    for(i=istart; i<iend; i++){
        x = (i+0.5f)*step_size;  accum += 4.0f/(1.0f+x*x); }
    l_sums[local_id] = accum;
    barrier(CLK_LOCAL_MEM_FENCE);
    reduce(l_sums, p_sums);
}
```

This code defines a kernel

It’s called SIMT, but GPUs are really vector-architectures with a block of work-items executing together (a subgroup in OpenCL or a warp in CUDA)

Submit a kernel to an OpenCL command queue or a CUDA stream

Organize work-items into work-groups and map onto an N dimensional index space. CUDA calls this a thread-block

OpenCL index space is called an NDRange. CUDA calls this a Grid
OpenMP: mapping the parallelism

- OpenMP defines three levels of parallelism:
  1. Teams
  2. Parallel threads
  3. SIMD

- But GPU hardware really has two levels of parallelism:
  1. Compute units
  2. Processing elements

- Implementations have flexibility in how they associate OpenMP concepts to the underlying hardware

- LLVM-based compilers, including Cray CCE >= 9, usually associate:
  - OpenMP teams to compute units
  - OpenMP threads to processing elements
  - OpenMP SIMD is ignored
- Cray classic compiler maps SIMD to processing elements instead
How is this parallelism applied?

• Consider:
  #pragma omp teams distribute

• Loop iterations distributed between teams
• Remember, you can’t synchronize between teams
• So all iterations are **independent**
• Implementations can, and will, share the work across the whole GPU:
  – OpenMP teams being mapped to processing elements
  – Doesn’t matter how the work-items are grouped into work-groups (compute units) as **no** synchronisation
• Behaves somewhat like SIMD auto-vectorization
What parallelism are you getting?

• With more than one possible mapping, sometimes you need to find out what is really happening.

• Compiler documentation:
  – Cray: man intro_openmp

• Compiler output:
  – In CCE 10, -fsave-loopmark flag

• Profiling:
  – $ nvprof --print-gpu-trace
  – Look for the number of threads per block, and number of blocks
  – Combine that with knowledge of pragma and number of loop iterations
CUDA Toolkit: NVProf/nsys

Trace profiling: nvprof --print-gpu-trace .exe <params>

```bash
> nvprof --print-gpu-trace .flow.omp4 flow.params
Problem dimensions 4000x4000 for 1 iterations.

Some OpenMP performance portability results

• To test performance we use a mixture of synthetic benchmarks and mini-apps.

• We compare against device-specific code written in OpenMP 3.0 and CUDA.

• We eventually use OpenMP 4.x to run on every diverse architecture that we believe is currently supported.

• Our initial expectations were low – but initial results we produced in 2016 were promising.
Performance?

Immediately we see impressive performance compared to CUDA

Clearly the Cray compiler leverages the existing OpenACC backend

Even with OpenMP 4.5 there is still no way of targeting shared memory directly.

This is set to come in with OpenMP 5.0, and Clang supports targeting address spaces directly.

Martineau, M., McIntosh-Smith, S. Gaudin, W., Evaluating OpenMP 4.0's Effectiveness as a Heterogeneous Parallel Programming Model, 2016, HIPS’16

Third party names are the property of their owners.
Performance?

We found that Cray’s OpenMP 4.0 implementation achieved great performance on a K20x.

We have seen these figures continually improve as the languages have matured.

Martineau, M., McIntosh-Smith, S. Gaudin, W., Assessing the Performance Portability of Modern Parallel Programming Models using TeaLeaf, 2016, CC-PE.
How do you get good performance?

• Our findings so far: You can achieve good performance on GPUs with OpenMP 4.x.

• We achieved this by:

  • Keeping data resident on the device for the greatest possible time.

  • Collapsing loops with the `collapse` clause, so there was a large enough iteration space to saturate the device (ideally >$10^4$ iterations to keep a modern GPU busy).

  • Using the BUD: `teams distribute parallel for simd`

  • Using the `simd` directive to vectorize inner loops.

  • Using `schedule(static, 1)` for coalescence (obsolete).

  • Using `nvprof` of course.
Can you do better?

Through extensive tuning of the compiler implementation we were able to execute CloverLeaf mini-app within 9% absolute runtime of hand optimized CUDA code…

Martineau, M., Bertolli, C., McIntosh-Smith, S., et al. *Broad Spectrum Performance Analysis of OpenMP 4.5 on GPUs, 2016, PMBS’16*

Third party names are the property of their owners.
Good. Performance… and Portability?

- Up until this point we had implicitly proven a good level of portability as we had successfully run OpenMP 4.x on many devices (Intel® CPU, Intel Xeon® Phi™ processors, NVIDIA® GPUs).

- The compiler support continually changes, improving performance, correctness and introducing new architectures.

- We keep tracking this improvement over time.
OpenMP has wide support, and *good* performance across all platforms.

Nice - but beware of the caveat.

There is a **MAJOR** caveat - the directives were not identical.

Martineau, M., McIntosh-Smith, S. Gaudin, W., *Pragmatic Performance Portability with OpenMP 4.x*, 2016, IWOMP’16

Third party names are the property of their owners.
The worst case scenario

// CCE targeting NVIDIA GPU
#pragma omp target teams distribute simd
for(...) {
}

// Clang targeting NVIDIA GPU
#pragma omp target teams distribute parallel for schedule(static, 1)
for(...) {
}

// GCC 6.1 target AMD GPU
#pragma omp target teams distribute parallel for
for(...) {
}

// ICC targeting Intel Xeon Phi
#pragma omp target if(offload)
#pragma omp parallel for simd
for(...) {
}

Four different ways of writing for the same kernel…
The answer:

• If you can, just use #pragma omp loop!

• If you can’t, use most compilers would accept the combined construct:
  - #pragma omp target teams distribute parallel for

• This does not generalize to all algorithms unfortunately, but the majority can be adapted.

• The construct makes a lot of guarantees to the compiler and it is very easy to reason about for good performance.
Caveats

If you can - just use loop!

- Real applications will have algorithms that are structured such that they can’t immediately use the combined construct.

- The handling of clauses, such as collapse, can be tricky from a performance portability perspective.

- Don’t be misguided… performance is possible without using the combined construct, but it likely won’t be consistent across architectures.
Performance
Portability

• Feature complete implementations will allow you to write performant code, and they will allow you to write portable code.

• To get both will likely require algorithmic changes, and a careful approach to using OpenMP 4.5 in your application.

• Avoid setting `num_teams(nt)` and `thread_limit(tl)` if you can, this is definitely not going to be performance portable.

• Use `collapse(n)` in all situations where you expect the trip count of the outer loop to be small, but be aware that it can have a negative effect on CPU performance.

• Use the combined construct whenever you can.

If you can - just use loop!

Compiler Support for OpenMP target

- **NVIDIA** support much of OpenMP for GPUs in NVHPC.

- **Intel** began support for OpenMP 4.0 targeting their Intel Xeon Phi coprocessors in 2013 (compiler version 15.0). Compiler version 17.0 and later versions support OpenMP 4.5. Compiler in oneAPI supports offload to Intel GPUs.

- **Cray** provided the first vendor supported implementation targeting NVIDIA GPUs in late 2015. CCE 9 moved to LLVM base. The latest version of CCE now supports all of OpenMP 4.5 and some of OpenMP 5.

- **AMD** AOMP compiler supports offload to AMD GPUs.

- **IBM** has recently completed a compiler implementation using Clang, that fully supports OpenMP 4.5. This is being introduced into the Clang main trunk.

- **LLVM/Clang** supports OpenMP 4.5 offload to NVIDIA GPUs. Used as base for many compilers.

- **GCC 6.1** introduced support for OpenMP 4.5. **GCC 10** can target Intel Xeon Phi, AMD GCN GPUs and NVIDIA GPUs.

- **PGI** compilers don’t currently support OpenMP on GPUs (but they do for CPUs).

OpenMP compiler information: [https://www.openmp.org/resources/openmp-compilers-tools/](https://www.openmp.org/resources/openmp-compilers-tools/)

Third party names are the property of their owners.
OpenMP 5.x and ecosystem

- OpenMP 5 adds features to make writing performance portable programs simpler.
- Highlighting some applicable to target offload:
  - Interop
  - Mappers
  - Unified Shared Memory (USM) and requires
  - Function variants
  - Reverse offload
  - OMP_TARGET_OFFLOAD
  - Reduction result mapping
    - Reduction variables now implicitly map(tofrom)
OpenMP 5.0: Pointer attachment

• Map pointer variables and initialize them to point to device memory.

```c
struct {
    char *p;
    int a;
} S;
S.p = malloc(100);

#pragma omp target data map(S)
{
    #pragma omp target map(S.p[:100])
    { // attach(S.p) = device_malloc(100);
        ...
    }
    // device_free(S.p[:100]), detach(S.p);
}

free(S.p);
```

Map the structure S

Map 100 elements pointed to by S.p and update the pointer S.p on the device to point at the mapped elements.
The **declare mapper** directive declares a user-defined *mapper* for a given type.

A *mapper* defines a method for mapping complex data structures to a target device.

A mapper may be used to implement a *deep copy* of pointer structure elements.

typedef struct myvec {
    size_t len;
    double *data;
} myvec_t;

```c
#pragma omp declare mapper(myvec_t v)
    use_by_default map(v, v.data[:v.len])
size_t num = 50;
myvec_t *v = alloc_array_of_myvec(num);

#pragma omp target map(v[:50])
{ 
    do_something_with_v(&v);
}
```

Declare a mapper that declares how a structure variable of type myvec_t is mapped.

Use the mapper for myvec_t to map an array of type myvec_t.
OpenMP 5.0: #pragma omp requires

- Code requires specific features, e.g. shared memory between host and devices.

```c
typedef struct mypoints {
    struct myvec * x;
    struct myvec scratch;
    double useless_data[500000];
} mypoints_t;

#pragma omp requires unified_shared_memory

mypoints_t p = new_mypoints_t();

#pragma omp target
{
    do_something_with_p(&p);
}
```

This code assumes that the host and device share memory.

No map clauses. All of p is shared between the host and device.
OpenMP 5.0: function variants

- Declare a device specific version *(variant)* of a function.
  - The variant is optimized for the device.

```c
double a[N], b[N], c[N];

#pragma omp declare variant(fastFUNC) match(target)
double FUNC(double, double);

#pragma omp target
for (int i=0; i<N; i++)
a[i] = FUNC(b[i], c[i]);
```

Declare `fastFUNC` as a variant for `FUNC` when executing in a target region.

Call `fastFUNC` here instead of `FUNC`
OpenMP 5.0: reverse offload

- Execute a region of code back on the host from within a target region.
  - A target device may not be able to execute this code.

```c
double a[N], b[N], c[N];

#pragma omp target map(to:b,c) map(from:a)
{
  for (int i=0; i<N; i++)
    a[i] = FUNC(b[i], c[i]);

  #pragma omp target device(ancestor:1)
  printf_array(a);

  ...
}
```
OpenMP 5.0: accelerators miscellaneous

• Implicit **declare target** directives
  – No need to put **omp declare target** on every function if compiler can determine function is used on a target device.

• Allow **declare target** on C++ classes with virtual members.

• **defaultmap**(implicit-behavior[:variable-category])
  – E.g. defaultmap(to:aggregate), defaultmap(alloc:scalar)

• **OMP_TARGET_OFFLOAD**  MANDATORY | DISABLED
  – A new environment variable that controls device constructs.

• C/C++ array shaping
  – E.g. int *p; #pragma omp map( ([10][1024*1024])p[i])

• Many other clarifications…

To learn more about OpenMP

The OpenMP web site has a great deal of material to help you with OpenMP. [www.openmp.org](http://www.openmp.org)

Reading the spec is painful … but each spec has a collection of examples. Study the examples, don’t try to read the specs.

Since the specs are written ONLY for implementors … programmers need the OpenMP Books to master OpenMP.

Start here … learn the basics and build a foundation for the future

Learn advanced features in OpenMP including tasking and GPU programming (up to version 4.5)

Learn all the details of GPU programming with OpenMP (up to version 5.2)

Coming in November 2023
Thank you for joining us!

Tutorial materials are available here: https://github.com/uob-hpc/openmp-tutorial
Live Q&A and Discussion
Appendices

• OpenMP and C++
OpenMP and C++

- OpenMP and C++ version compatibility
- Mapping class member variables and functions
OpenMP 4.x C++ support

- The OpenMP API specification refers to ISO/IEC 14882:1998 as C++98!
- Think programming “C in C++”.

```cpp
foo(std::vector<double> &x) {
    #pragma omp target data map(x)
    {  ... }
}
```

```cpp
foo(std::vector<double> &x) {
    double *pv = &x[0];
    #pragma omp target data map(pv[:x.size()])
    {  ... }
}
```

You cannot map STL containers!
Mapping class member variables and functions

```cpp
struct typeX { int a; }
class typeY {
    int a;
    public:
        int foo() { return a^0x01; }
};
#pragma omp declare target to(typeY::foo)

#pragma omp declare target
struct typeX varX; // ok
#pragma omp end declare target
class typeY varY; // ok

void foo()
{
    #pragma omp target map(varY)
    {
        varX.a = 100; // ok
        varY.foo(); // ok
    }
}
```

The member function `typeY::foo()` can be accessed on a target device as long as it appears in a declare target directive and is not virtual.

class Matrix
{
    Matrix(int n) {
        len = n;
        v = new double[len];
        #pragma omp target enter data map(alloc:v[0:len])
    }

    ~Matrix() {
        #pragma omp target exit data map(delete:v[0:len])
        delete[] v;
    }

    private:
    double* v;
    int len;
};

Use delete map type since the corresponding host data is free’d after the deconstructor.
OpenMP 5.0 C++ support

• OpenMP starts to support modern C++
• The OpenMP API specification refers to ISO/IEC 14882:{2011,2014,2017} as C++11, C++14, and C++17 respectively.

• The use of the following features may result in unspecified behavior.
  – Alignment support
  – Standard layout types
  – Allowing move constructs to throw
  – Defining move special member functions
  – Concurrency
  – Data-dependency ordering: atomics and memory model
  – Additions to the standard library
  – Thread-local storage
  – Dynamic initialization and destruction with concurrency
  – C++11 library
  – Sized deallocation (C++14)
  – What signal handlers can do (C++14)
Our running example: Jacobi solver

• An iterative method to solve a system of linear equations
  – Given a matrix A and a vector b find the vector x such that \( Ax=b \)

• The basic algorithm:
  – Write A as a lower triangular (L), upper triangular (U) and diagonal matrix
    \[ Ax = (L+D+U)x = b \]
  – Carry out multiplications and rearrange
    \[ Dx=b-(L+U)x \rightarrow x = (b-(L+U)x)/D \]
  – Iteratively compute a new x using the x from the previous iteration
    \[ X_{new} = (b-(L+U)x_{old})/D \]

• Advantage: we can easily test if the answer is correct by multiplying our final x by A and comparing to b

• Disadvantage: It takes many iterations and only works for diagonally dominant matrices
Jacobi Solver

Iteratively update $x_{new}$ until the value stabilizes (i.e. change less than a preset TOL)

```c
<<< allocate and initialize the matrix A >>>
<<< and vectors x1, x2 and b >>>

while((conv > TOL) && (iters<MAX_ITERS))
{
    iters++;
    for (i=0; i<Ndim; i++){
        xnew[i] = (TYPE) 0.0;
        for (j=0; j<Ndim;j++){
            if(i!=j)
                xnew[i]+= A[i*Ndim + j]*xold[j];
        }
        xnew[i] = (b[i]-xnew[i])/A[i*Ndim+i];
    }
    // test convergence
    conv = 0.0;
    for (i=0; i<Ndim; i++){
        tmp = xnew[i]-xold[i];
        conv += tmp*tmp;
    }
    conv = sqrt((double)conv);
    // swap pointers for next iteration
    TYPE* tmp = xold;
    xold = xnew;
    xnew = tmp;
}
} // end while loop
```
Exercise: Jacobi solver

• Start from the provided jacobi_solver program. Verify that you can run it serially.
• Parallelize for a CPU using the *parallel for* construct on the major loops
• Use the target directive to run on a GPU.
  – #pragma omp target
  – #pragma omp target map(to:list) map(from:list) map(tofrom:list)
while((conv > TOL) && (iters<MAX_ITERS))
{
    iters++;

    #pragma omp target map(tofrom:xnew[0:Ndim],xold[0:Ndim]) \
        map(to:A[0:Ndim*Ndim], b[0:Ndim] )
for (i=0; i<Ndim; i++){
    xnew[i] = (TYPE) 0.0;
    for (j=0; j<Ndim;j++){
        if(i!=j)
            xnew[i]+= A[i*Ndim + j]*xold[j];
    }
    xnew[i] = (b[i]-xnew[i])/A[i*Ndim+i];
}
Jacobi Solver (Par Targ, 2/2)

//
// test convergence
//
conv = 0.0;
#pragma omp target map(to:xnew[0:Ndim],xold[0:Ndim]), map(tofrom:conv)
for (i=0; i<Ndim; i++){
    tmp = xnew[i]-xold[i];
    conv += tmp*tmp;
}
conv = sqrt((double)conv);

TYPE* tmp = xold;
xold = xnew;
xnew = tmp;

} // end while loop
